(54) Titre : DISPOSITIF DE MODULATION D'UN FAISCEAU DE LUMIERE  
(54) Title: MODULATING A LIGHT BEAM

(57) Abrégé/Abstract:

A modulator (10) for modulating incident rays of light, the modulator having several equally spaced beam elements (18), each having a light reflective planar surface. The beam elements are arranged and supported (12) parallel to each other, with their reflective surfaces parallel. During operation, the elements remain parallel, but the modulator moves the beams so that the perpendicular spacing of their reflective surfaces changes between two configurations. In both configurations, the spacing equals  $m/4$  times the wavelength of incident light. In the first configuration,  $m$  equals an even whole number or zero, and the modulator acts to reflect the incident rays of light as a plane mirror. In the second configuration,  $m$  equals an odd number and the modulator diffracts the incident rays as they are reflected.

MODULATING A LIGHT BEAM

BACKGROUND OF THE INVENTION

Field of the Invention

This invention relates to a method and apparatus for modulating a light beam and more particularly to the use of a reflective, deformable diffraction grating for performing such modulation.

Brief Description of the Prior Art

Devices which modulate a light beam, e.g. by altering the amplitude, frequency or phase of the light, find a number of applications. An example of such a device is a spatial light modulator (SLM) which is an electronically or optically controlled device which consists of one or two-dimensional reconfigurable patterns of pixel elements, each of which can individually modulate the amplitude, phase or polarization of an optical wavefront.

These devices have been extensively developed, particularly for applications in the areas of optical processing and computing. They can perform a variety of functions such as: analog multiplication and addition, signal conversion (electrical-to-optical, incoherent-to-coherent, amplification, etc.), nonlinear operations and short term storage. Utilizing these functions, SLMs have seen many different applications from display technology to optical signal processing. For example, SLMs have been used as optical correlators (e.g., pattern recognition devices, programmable holograms), optical matrix processors (e.g., matrix multipliers, optical cross-bar switches with broadcast capabilities, optical neural networks, radar beam forming), digital optical architectures (e.g., highly parallel optical computers) and displays.

The requirements for SLM technology depend strongly on the application in mind: for example, a display requires low bandwidth but a high dynamic range while

SUBSTITUTE SHEET

1 optical computers benefit from high response times but do  
2 not require such high dynamic ranges. Generally, systems  
3 designers require SLMs with characteristics such as: high  
4 resolution, high speed (kHz frame rates), good gray scale,  
5 high contrast ratio or modulation depth, optical flatness,  
6 VLSI compatible, easy handling capability and low cost.  
7 To date, no one SLM design can satisfy all the above  
8 requirements. As a result, different types of SLMs have  
9 been developed for different applications, often resulting  
10 in trade-offs.

11 Texas Instruments, for instance, has developed a  
12 "Deformable Mirror Device (DMD)" that utilizes an  
13 electromechanical means of deflecting an optical beam.  
14 The mechanical motions needed for the operation of the DMD  
15 are relatively large and, as a result, the bandwidths are  
16 limited to tens of kilohertz. This device, however, gives  
17 good contrast ratios and high-resolution and is,  
18 furthermore, compatible with CMOS, and other low power  
19 technologies.

20 Nematic and ferroelectric liquid crystals have also  
21 been used as the active layer in several SLMs. Since the  
22 electrooptic effect in liquid crystals is based on the  
23 mechanical reorientation of molecular dipoles, it is to be  
24 expected that liquid crystals are faster than the DMD-type  
25 devices. Modulators using ferroelectric liquid crystals  
26 have exhibited moderate switching speeds (150  $\mu$ sec to 100  
27 nsec), low-power consumption, VLSI compatible switching  
28 voltages (5-10 V), high extinction ratios, high resolution  
29 and large apertures. However, these devices suffer from  
30 the drawbacks of limited liquid crystal lifetimes and  
31 operating temperature ranges. In addition, the  
32 manufacturing process is complicated by alignment problems  
33 and film thickness uniformity issues.

34 Magneto optic modulation schemes have been used to  
35 achieve faster switching speeds and to provide an optical  
36 pattern memory cell. Although these devices, in addition  
37 to achieving fast switching speeds, can achieve large  
38 contrast ratios, they suffer from a low (<10%) throughput

1 efficiency and are, therefore, often unsuitable for many  
2 applications.

3 The need is therefore for a light modulation device  
4 which overcomes these drawbacks.

5 Beside SLMs, another area of use of light modulators  
6 is in fiber optics. Fiber optic modulators are  
7 electronically controlled devices that modulate light  
8 intensity and are designed to be compatible with optical  
9 fibers. For high speed communication applications,  
10 lithium niobate ( $\text{LiNbO}_3$ ) traveling wave modulators  
11 represent the state-of-the-art, but there is a need for  
12 low power, high efficiency, low loss, inexpensive fiber  
13 optic modulators, that can be integrated with silicon  
14 sensors and electronics, for data acquisition and medical  
15 applications. A typical use of a modulator combined  
16 with fiber optic technology, for example, is a data  
17 acquisition system on an airplane which consists of a  
18 central data processing unit that gathers data from remote  
19 sensors. Because of their lightweight and electro-  
20 magnetic immunity characteristics, fiber optics provide an  
21 ideal communication medium between the processor and the  
22 sensors which produce an electrical output that must be  
23 converted to an optical signal for transmission. The most  
24 efficient way to do this is to have a continuous wave  
25 laser at the processor and a modulator operating in  
26 reflection at the sensor. In this configuration, it is  
27 also possible to deliver power to the sensor over the  
28 fiber.

29 In this type of application the modulator should  
30 operate with high contrast and low insertion loss to  
31 maximize the signal to noise ratio and have low power  
32 consumption. It should further be compatible with silicon  
33 technology because the sensors and signal conditioning  
34 electronics used in these systems are largely implemented  
35 in silicon.

36 Another use of a modulator combined with fiber optic  
37 technology is in the monitoring of sensors that are  
38 surgically implanted in the human body. Here optical  
39 fibers are preferred to electrical cables because of their

1 galvanic isolation, and any modulator used in these  
2 applications should exhibit high contrast combined with  
3 low insertion loss because of signal to noise  
4 considerations. Furthermore, as size is important in  
5 implanted devices, the modulator must be integratable with  
6 silicon sensors and electronics.

7       There exist no prior art devices that have the  
8 characteristics enumerated above. Modulators based on the  
9 electro-optic, Franz-Keldysh, Quantum-Confined-Stark or  
10 Wannier-Stark effect in III-V semiconductors have high  
11 contrast and low insertion loss, but are expensive and not  
12 compatible with silicon devices. Waveguide modulators  
13 employing glass or epi-layers on silicon, require too much  
14 area and too complex fabrication to be easily integratable  
15 with other silicon devices. Silicon modulators that do  
16 not employ waveguides and that are based on the plasma  
17 effect, require high electrical drive power and do not  
18 achieve high contrast.

19       The need is therefore for a light modulator which can  
20 be used with fiber optic technology with low power, high  
21 efficiency, low loss, low cost and compatibility with  
22 multimode optical fibers and silicon technology.

SUMMARY OF THE INVENTIONObjects of the Invention

Accordingly, it is an object of this invention to provide a light modulator which alone or together with other modulators exhibits most of the following characteristics: high resolution, high speed (Khz frame rates), gray levels (100 levels), high contrast ratio or modulation depth, optical flatness, VLSI compatible, easy handling capability and low cost.

A further object of this invention is to provide a light modulator which has a tolerance for high optical power and good optical throughput.

Yet another object of this invention is to provide a light modulator which is compatible with CMOS technology.

Still another object of this invention is to provide a light modulator capable of use with fiber optic technology.

A final object of this invention is to provide a light modulator which is capable of modulating white light to produce colored light.

Summary

Briefly a presently preferred embodiment of this invention includes a modulator for modulating incident beams of light, the modulator comprising a plurality of equally spaced apart grating elements, each of which includes a light reflective planar surface. The elements are arranged parallel to each other with their light reflective surfaces parallel to each other. The modulator includes means for supporting the elements in relation to one another and means for moving the elements relative to one another so that the elements move between a first configuration wherein the modulator acts to reflect the incident beam of light as a plane mirror, and a second configuration wherein the modulator diffracts the incident beam of light as it is reflected therefrom. In operation, the light reflective surfaces of

1 the elements remain parallel to each other in both the  
2 first and the second configurations and the perpendicular  
3 spacing between the reflective surfaces of adjacent  
4 elements is equal to  $m/4$  times the wavelength of the  
5 incident beam of light, wherein  $m$  = an even whole number  
6 or zero when the elements are in the first configuration  
7 and  $m$  = an odd number when the elements are in the second  
8 configuration.

9 One embodiment of this invention includes a  
10 reflective deformable grating light modulator, with a  
11 grating amplitude that can be controlled electronically,  
12 consisting of a reflective substrate with a deformable  
13 grating suspended above it. In its undeformed state, with  
14 no voltage applied between the elements of the grating and  
15 the substrate, the grating amplitude is one half of the  
16 wavelength of the incoming light. Since the round-trip  
17 path difference between the light reflected from the top  
18 and bottom of the grating is one wavelength, no  
19 diffraction occurs. When a voltage is applied between the  
20 grating elements and the substrate, the electrostatic  
21 force pulls the elements down to cause the grating  
22 amplitude to become one quarter of the wavelength so that  
23 reflections from the elements and the substrate add  
24 destructively, causing the light to be diffracted. If the  
25 detection system for the reflected light has a numerical  
26 aperture which accepts only the zero order beam, a  
27 mechanical motion of only one quarter of a wavelength is  
28 sufficient to modulate the reflected light with high  
29 contrast.

30 Typically the grating is formed by lithographically  
31 etching a film made of silicon nitride, aluminum, silicon  
32 dioxide or any other material which can be  
33 lithographically etched.

34 The deformable grating modulator of this invention  
35 has the advantage that it is implemented in silicon  
36 technology, using micromachining and sacrificial etching  
37 of thin films to fabricate the gratings. Circuitry for  
38 addressing and multiplexing can be manufactured on the  
39 same silicon substrate and thus be directly integrated

1 with the modulator. Direct integration with electronics  
2 is an important advantage over non-silicon based  
3 technologies like liquid crystal and electrooptic SLMs.  
4 Moreover, the device demonstrates simplicity of  
5 fabrication and can be manufactured with only a few  
6 lithographic steps.

7 A further advantage of the deformable grating  
8 modulator is that because the deformable grating modulator  
9 utilizes diffraction rather than deflection of a light  
10 beam, the required mechanical motions are reduced from  
11 several microns (as in deformable mirror devices) to  
12 tenths of a micron, thus allowing for a potential three  
13 orders of magnitude in increase in speed. This speed is  
14 comparable to the fastest liquid crystal modulators, but  
15 without the device suffering the same complexity in the  
16 manufacturing process.

17 Still a further advantage of these devices is that  
18 the required motion of the grating elements is only one  
19 quarter of a wavelength, which means that elements with  
20 high resonance frequencies can be used.

21 These and other objects and advantages of the present  
22 invention will no doubt become apparent to those skilled  
23 in the art after having read the following detailed  
24 description of the preferred embodiment which is  
25 illustrated in the several figures of the drawing.

#### 26 IN THE DRAWING

27  
28 This invention will now be further illustrated with  
29 reference to the accompanying drawing in which:

30 FIG. 1(a)-(d) are cross-sections through a silicon  
31 substrate illustrating the manufacturing process of a  
32 reflective, deformable diffraction grating according to  
33 one embodiment of the invention;

34 FIG. 2 is an isometric, partially cut-away view of  
35 the diffraction grating, the manufacture of which is  
36 illustrated in FIG. 1.

37 FIG. 3 illustrates the operation of the grating of  
38 FIG. 2 in its "non-defracting" mode;

-8-

1 FIG. 4 illustrates the operation of the grating of  
2 FIG. 3 in its "diffracting" mode;

3 FIG. 5 is a cross-section similar to that in FIG. 3,  
4 illustrating an alternative embodiment of the grating in  
5 its "non-diffracting" mode;

6 FIG. 6 is a cross-section similar to that in FIG. 4,  
7 illustrating the grating in FIG. 5 in its "diffracting"  
8 mode;

9 FIG. 7 is a pictorial view illustrating a further  
10 embodiment of the grating;

11 FIG. 8 is a cross-section along line 8-8 in FIG. 7;

12 FIG. 9 is a graphical representation of the  
13 modulation of a laser beam by the grating of the  
14 invention;

15 FIG. 10 is an illustration of how the diffraction  
16 grating of the invention can be combined with other  
17 gratings to form a complex modulator; and

18 FIG. 11 illustrates the operation of the grating in  
19 the modulation of white light to produce color.  
20

#### 21 DESCRIPTION OF PREFERRED EMBODIMENTS

22 The fabrication steps required to produce a  
23 reflective deformable grating 10 according to this  
24 invention are illustrated in FIG. 1(a)-(d).

25 The first step, as illustrated in FIG. 1(a), is the  
26 deposition of an insulating layer 11 made of stoichiometric  
27 silicon nitride topped with a buffer layer of silicon  
28 dioxide followed by the deposition of a sacrificial  
29 silicon dioxide film 12 and a low-stress silicon nitride  
30 film 14, both 213 nm thick, on a silicon substrate 16.  
31 The low-stress silicon nitride film 14 is achieved by  
32 incorporating extra silicon (beyond the stoichiometric  
33 balance) into the film, during the deposition process.  
34 This reduces the tensile stress in the silicon nitride  
35 film to roughly 200 MPa.

36 In the second step, which is illustrated in FIG.  
37 1(b), the silicon nitride film 14 is lithographically  
38 patterned into a grid of grating elements in the form of  
39 elongate elements 18. In an individual grating, all the

1 elements are of the same dimension and are arranged  
2 parallel to one another with the spacing between adjacent  
3 elements equal to the beam width. Depending on the design  
4 of the grating, however, the elements could typically be  
5 1, 1.5 or 2  $\mu\text{m}$  wide with a length that ranges from 10  $\mu\text{m}$  to  
6 120  $\mu\text{m}$ . After this lithographic patterning process a  
7 peripheral silicon nitride frame 20 remains around the  
8 entire perimeter of the upper surface of the silicon  
9 substrate 16. This frame 20 is further illustrated in  
10 FIG. 2 and will be more fully described below with  
11 reference to that figure.

12 After the patterning process of the second step, the  
13 sacrificial silicon dioxide film 12 is etched in  
14 hydrofluoric acid, resulting in the configuration  
15 illustrated in FIG. 1(c). It can be seen that each  
16 element 18 now forms a free standing silicon nitride  
17 bridge, 213 nm thick, which is suspended a distance of  
18 213nm (this being the thickness of the etched away  
19 sacrificial film 12) clear of the silicon substrate. As  
20 can further be seen from this figure the silicon dioxide  
21 film 12 is not entirely etched away below the frame 20 and  
22 so the frame 20 is supported, a distance of 213 nm, above  
23 the silicon substrate 16 by this remaining portion of the  
24 silicon dioxide film 12. The elements 18 are stretched  
25 within the frame and kept straight by the tensile stress  
26 imparted to the silicon nitride film 14 during the  
27 deposition of that film.

28 The last fabrication step, illustrated in FIG. 1(d),  
29 is sputtering, through a stencil mask, of a 50 nm thick  
30 aluminum film 22 to enhance the reflectance of both the  
31 elements 18 and the substrate 16 and to provide a first  
32 electrode for applying a voltage between the elements and  
33 the substrate. A second electrode is formed by sputtering  
34 an aluminum film 24, of similar thickness, onto the base  
35 of the silicon substrate 16.

36 The final configuration of the grating is illustrated  
37 in FIG. 2. Here it can be seen that the elements 18  
38 together with the frame 20 define a grating which, as will

213 3335

PCT/US 93/03939  
IPEA/US 19 NOV 1993

-9A-

- 1 be later explained, can be used for modulating a light
- 2 beam. Furthermore, and as can be gathered from the above

1 described manufacturing process, the frame 20 is formed  
2 integrally with the elements 18 and thus provides a  
3 relatively rigid supporting structure which maintains the  
4 tensile stress within the elements 18. In so doing, and  
5 as the frame 20 is supported by the remainder of the  
6 silicon dioxide film 12 that was not etched away, the  
7 elements are kept straight and a distance of 213 nm above  
8 the surface of the silicon substrate 16.

9 The operation of the deformable grating 10, formed by  
10 the above process, is illustrated with reference to FIG.  
11 3 and 4. Before commencing the description of how the  
12 grating operates, however, it should be recalled that, in  
13 this case, each of the elements 18 are 213 nm thick and  
14 are suspended a distance of 213 nm clear of the substrate  
15 16. This means that the distance from the top of each  
16 element to the top of the substrate is 426 nm. Similarly,  
17 the distance between the top of the reflective surface on  
18 the elements to the top of the reflective surface on the  
19 substrate is also 426 nm. This distance is known as the  
20 grating amplitude.

21 In FIG. 3 the grating 10 is shown with no voltage  
22 applied between the substrate 16 and the individual  
23 elements 18, and with a lightwave, generally indicated as  
24 26, of a wavelength  $\lambda = 852$  nm incident upon it. The  
25 grating amplitude of 426 nm is therefore equal to half of  
26 the wavelength of the incident light and, therefore, the  
27 total path length difference for the light reflected from  
28 the elements and from the substrate equals the wavelength  
29 of the incident light. As a result, light reflected from  
30 the elements and from the substrate add in phase and the  
31 grating 10 acts to reflect the light as a flat mirror.

32 However, as illustrated in FIG. 4, when a voltage is  
33 applied between the elements 18 and the substrate 16 the  
34 electrostatic forces pull the elements 18 down onto the  
35 substrate 16, with the result that the distance between  
36 the top of the elements and the top of the substrate is  
37 now 213 nm. As this is one quarter of the wavelength of  
38 the incident lights, the total path length difference for

213 3335

PCT/US 93/03939

IPEAS 19 NOV 1993

-10A-

- 1 the light reflected from the elements and from the
- 2 substrate is

2133335

-11-

1 now one half of the wavelength (426 nm) of the incident  
2 light and the reflections interfere destructively, causing  
3 the light to be diffracted, indicated as 28.

4 Thus, if this grating is used in combination with a  
5 system, for detecting the reflected light, which has a  
6 numerical aperture sized to detect one order of diffracted  
7 light from the grating e.g., the zero order, this grating  
8 can be used to modulate the reflected light with high  
9 contrast.

10 In FIGS. 5 and 6 an alternative embodiment of the  
11 diffraction grating 30 of the invention is illustrated.  
12 In this embodiment the grating 30 consists of a plurality  
13 of equally spaced, equally sized, fixed elements 32 and a  
14 plurality of equally spaced, equally sized, movable  
15 elements 34 in which the movable elements 34 lie in the  
16 spaces between the fixed elements 32. Each fixed element  
17 32 is supported on and held in position by a body of  
18 supporting material 36 which runs the entire length of the  
19 fixed element 32. The bodies of material 36 are formed  
20 during a lithographic etching process in which the  
21 material between the bodies 36 is removed.

22 As can be seen from FIG. 5 the fixed elements 32 are  
23 arranged to be coplanar with the movable elements 34 and  
24 present a flat upper surface which is coated with a  
25 reflective layer 38. As such the grating 30 acts as a  
26 flat mirror when it reflects incident light, however, when  
27 a voltage is applied between the elements and an electrode  
28 40 at the base of the grating 30 the movable elements 34  
29 move downwards as is illustrated in FIG. 6. By applying  
30 different voltages the resultant forces on the elements 34  
31 and, therefore, the amount of deflection of the movable  
32 elements 34 can be varied. Accordingly, when the grating  
33 amplitude (defined as the perpendicular distance  $d$  between  
34 the reflective layers 38 on adjacent elements) is  $m/4$   
35 times the wavelength of the light incident on the grating  
36 30, the grating 30 will act as a plane mirror when  $m = 0$ ,  
37 2, 4... (i.e. an even number or zero) and as a reflecting  
38 diffraction grating when  $m = 1, 3, 5...$  (i.e. an odd  
39 number). In this manner the grating 30 can operate to

1 modulate incident light in the same manner as the grating  
2 10 illustrated in FIGS. 1 to 4.

3 Yet another embodiment of the diffraction grating of  
4 the invention is illustrated in FIGS. 7 and 8. As with  
5 the grating 10 in FIGS. 1 to 4 this grating 41 consists of  
6 a sacrificial silicon dioxide film 42, a silicon nitride  
7 film 44 and a substrate 46. In this embodiment, however,  
8 the substrate 46 has no reflective layer formed thereon  
9 and only the silicon nitride film 44 has a reflective  
10 coating 45 formed thereon. As is illustrated in FIG. 7  
11 the deformable elements 48 are coplanar in their  
12 undeformed state and lie close to one another so that  
13 together they provide a substantially flat reflective  
14 surface. The elements 48 are, however, formed with a neck  
15 50 at either end, which is off-center of the longitudinal  
16 center line of each of the elements 48.

17 When a uniformly distributed force, as a result of an  
18 applied voltage for example, is applied to the elements 48  
19 the resultant force  $F$ , for each element 48, will act at  
20 the geometric center 52 of that element. As each  
21 resultant force  $F$  is off-set from the axis of rotation 54  
22 (which coincides with the centerline of each neck 50), a  
23 moment of rotation or torque is applied to each element 48  
24 which results in a rotation of each element 48 about its  
25 axis 54 to the position 48' indicated in broken lines.  
26 This is known as "blazing" a diffraction grating.

27 As can be seen from FIG. 8, the reflective planes 56  
28 of the elements 48 remain parallel to each other even in  
29 this "blazed" configuration and therefore, the grating  
30 amplitude  $d$  is the perpendicular distance between the  
31 reflective surfaces of adjacent elements. This "blazed"  
32 grating will operate to diffract light in the same manner  
33 as a sawtooth grating.

34 Although not illustrated in any of FIGS. 1 to 8, it  
35 will be apparent that a deformable diffraction grating can  
36 be constructed in which, in its undeformed state, all the  
37 reflective elements are in the form of movable elements  
38 arranged parallel, adjacent and coplanar with each other.  
39 In this type of grating not only the grating

1 amplitude (i.e., the perpendicular distance between  
2 adjacent reflective surfaces) can be varied but also the  
3 average height of all the reflective surfaces can be  
4 changed by moving all the elements relative to a fixed  
5 datum. This arrangement has the advantage that both the  
6 amplitude and the phase of the reflected/diffracted light  
7 can be modulated.

8 The electrical, optical and mechanical  
9 characteristics of a number of modulators, similar in  
10 design to the modulator illustrated with reference to  
11 FIGS. 1 to 4 but of different dimensions were investigated  
12 by using a Helium Neon laser (of 633 nm wavelength)  
13 focused to a spot size of  $36\mu\text{m}$  on the center portion of  
14 each modulator. This spot size is small enough so that  
15 the curvature of the elements in the region where the  
16 modulator was illuminated can be neglected, but is large  
17 enough to allow the optical wave to be regarded as a plane  
18 wave and covering enough grating periods to give good  
19 separation between the zero and first order diffraction  
20 modes resulting from the operation of the grating. It was  
21 discovered that grating periods of (i.e.) the distance  
22 between the centerlines of two adjacent elements in the  
23 grating, 2, 3 and 4  $\mu\text{m}$  and a wavelength of 633 nm resulted  
24 in first order diffraction angles of  $18^\circ$ ,  $14^\circ$  and  $9^\circ$   
25 respectively.

26 One of these first order diffracted light beams was  
27 produced by using a 120  $\mu\text{m}$ -long grating modulator with 1.5  
28  $\mu\text{m}$ -wide elements at atmospheric pressure together with a  
29 HeNe light beam modulated at a bit rate of 500 kHz.  
30 detected by a low-noise photoreceiver and viewed on an  
31 oscilloscope. The resulting display screen 30 of the  
32 oscilloscope is illustrated in FIG. 9.

33 However, before proceeding with a discussion of the  
34 features illustrated in this figure, the resonant  
35 frequency of the grating elements should first be  
36 considered.

37 The resonant frequency of the mechanical structure of  
38 the grating of the invention was measured by driving the  
39 deformable grating modulator with a step function and

2133335

-14-

1 observing the ringing frequency. The area of the aluminum  
2 on the deformable grating modulator is roughly  $0.2 \text{ cm}^2$ ,  
3 which corresponds to an RC limited 3-dB bandwidth of 1 MHz  
4 with roughly 100 ohms of series resistance. This large RC  
5 time constant slowed down the step function, however,  
6 enough power existed at the resonant frequency to excite  
7 vibrations, even in the shorter elements. Although the  
8 ringing could be observed in normal atmosphere, the Q-  
9 factor was too low (approximately 1.5) for accurate  
10 measurements, so the measurements were made at a pressure  
11 of 150 mbar. At this pressure, the Q-factor rose to 8.6,  
12 demonstrating that air resistance is the major damping  
13 mechanism, for a grating of this nature, in a normal  
14 atmosphere.

15 Nonetheless, it was found that due to the high  
16 tensile stress in the elements, tension is the dominant  
17 restoring force, and the elements could therefore be  
18 modeled as vibrating strings. When this was done and the  
19 measured and theoretically predicted resonance frequencies  
20 compared, it was found that the theory is in good  
21 agreement with the experimental values, particularly when  
22 considering the uncertainty in tensile stress and density  
23 of the elements. As it is known that the bandwidth of  
24 forced vibrations of a mechanical structure is simply  
25 related to the resonance frequency and Q-factor, a Q-  
26 factor of 1.5 yields a 1.5 dB bandwidth of the deformable  
27 grating modulator 1.4 times larger than the resonance  
28 frequency. The range of bandwidths for these gratings is  
29 therefore from 1.8 MHz for the deformable grating  
30 modulator with  $120 \text{ }\mu\text{m}$  elements to 6.1 MHz for the  
31 deformable grating modulator with  $40 \text{ }\mu\text{m}$  elements.

32 Returning now to FIG. 9, it should be noted that with  
33 an applied voltage swing of 3 V, a contrast of 16dB for  
34 the  $120 \text{ }\mu\text{m}$ -long bridges could be observed. Here the term  
35 "modulation depth" is taken to mean the ratio of the  
36 change in optical intensity to peak intensity.

37 The input (lower trace 62) on the screen 60  
38 represents a pseudo-random bit stream switching between 0  
39 and -2.7 V across a set of grating devices on a 1 cm by 1

1 cm die. The observed switching transient with an initial  
2 fast part followed by a RC dominated part, is caused by  
3 the series resistance of the deformable grating modulator,  
4 which is comparable to a 50 ohm source resistance.

5 The output (upper trace 64) on the screen corresponds  
6 to the optical output of a low-noise photoreceiver  
7 detecting the first diffraction order of the grating used.  
8 The output (upper trace 64) from the deformable grating is  
9 high when the elements are relaxed and low when the  
10 elements are deflected. Ringing is observed only after  
11 the rising transient, because of the quadratic dependence  
12 of the electro-static force on the voltage (during  
13 switching from a voltage of -2.7 V to 0 V, the initial,  
14 faster part of the charging of the capacitor corresponds  
15 to a larger change in electro-static force, than when  
16 switching the opposite way). This ringing in the received  
17 signal indicates a decay close to critical damping.

18 Furthermore, it was found that because the  
19 capacitance increases as the elements are pulled toward  
20 the substrate, the voltage needed for a certain deflection  
21 is not a monotonically increasing function of this  
22 deflection. At a certain applied voltage condition, an  
23 incremental increase in the applied voltage causes the  
24 elements to be pulled spontaneously to the substrate (to  
25 latch) and this voltage is known as the "switching  
26 voltage" of the modulator. The switching voltage was  
27 found to be 3.2 V for gratings with 120  $\mu\text{m}$  long elements  
28 and, if it is assumed that tension dominates the restoring  
29 forces, the switching voltage is inversely proportional to  
30 the element length and therefore, the predicted switching  
31 voltage for 40  $\mu\text{m}$  long elements will be 9.6 V.

32 The importance of the switching voltage is that below  
33 this voltage, the deformable grating modulator can be  
34 operated in an analog fashion, however, if a voltage  
35 greater than the switching voltage is applied to the  
36 modulator it acts in a digital manner. Nonetheless, it is  
37 important to note that operating the modulator to the  
38 point of contact is desirable from an applications point  
39 of view, because as discussed above when the elements are

1 deflected electrostatically, an instability exists once  
2 the element deflection goes beyond the halfway point.  
3 This results in hysteretic behavior which will "latch" the  
4 element in the down position. This latching feature gives  
5 the modulator the advantages of an active matrix design  
6 without the need for active components. A further  
7 advantage of this latching feature is that once the  
8 element has "latched" it requires only a very small  
9 "holding voltage", much smaller than the original applied  
10 voltage, to keep the element in its latched configuration.  
11 This feature is particularly valuable in low power  
12 applications where efficient use of available power is  
13 very important.

14 Finally, it was discovered that when the elements of  
15 the modulators are brought into contact with the substrate  
16 they could stick. This can be solved by adding small  
17 ridges below the elements to reduce the contact area  
18 between the beams and the substrate and thereby reduce the  
19 sticking problem.

20 The use of the modulator of this invention in  
21 displays requires high yield integration of individual  
22 modulator devices into 2-D arrays of modulator devices.  
23 The modulator devices may be comprised of a single grating  
24 such as described above or may be comprised of multiple  
25 modulator components such as that illustrated in FIG. 10  
26 which shows a plurality of grating modulator components  
27 combined to form a single modulator device 65 which can be  
28 used to provide a gray-scale operation. Each of the  
29 individual modulator components 66, 68, 70, 72 consist of  
30 a number of elements and gray-scale can be obtained by  
31 addressing each modulator component in a binary-weighted  
32 manner. The hysteresis characteristic for latching (as  
33 described above) can be used to provide gray-scale  
34 variation without analog control of the voltage supplied  
35 to individual grating modulator elements.

36 In FIG. 11 the use of the grating, in combination  
37 with other gratings, for modulating white light to produce  
38 colored light is illustrated. This approach takes  
39 advantage of the ability of a grating to separate a light

2133335

-16A-

PCT/US 93/0393'

; IPEAUS 19 NOV 199'

1 spectrum into its constituent colors. By constructing  
2 modulator devices 73 including three separate red, green  
3 and blue modulation components 74, 76 and 78, each with a  
4 grating designed to diffract the appropriate color into an  
5 optical system (not shown), a color display which is white  
6 light

1 illuminated by a light beam 80 can be achieved. Although  
2 shown separated for purposes of illustration, it will be  
3 appreciated that the three modulation components 74, 76  
4 and 78 could be positioned contiguous to each other as are  
5 the components 66-72 in Fig. 10 to form a single modulator  
6 device 73. This approach is attractive for large area  
7 projection displays.

8 In summary, the reflective, deformable grating light  
9 modulator of this invention is a device which exhibits  
10 high resolution (40 by 40  $\mu\text{m}^2$  to 100  $\mu\text{m}^2$ ); high response  
11 times/large bandwidth (2 to 6 MHz); high contrast ratio  
12 (close to 100% modulation with a 3V switching voltage); is  
13 polarization independent and easy to use. This device  
14 also has tolerance for high optical power, has good  
15 optical throughput, is simple to manufacture, CMOS  
16 compatible, and has application in a wide range of fields  
17 including use as an SLM and with fiber optic technology.

18 Although the present invention has been described  
19 above in terms of specific embodiments, it is anticipated  
20 that alterations and modifications thereof will no doubt  
21 become apparent to those skilled in the art. It is  
22 therefore intended that the following claims be  
23 interpreted as covering all such alterations and  
24 modifications as fall within the true spirit and scope of  
25 the invention.

26 What is claimed is:

-18-

## CLAIMS:

1. A modulator for modulating an incident beam of light, comprising:

5 a plurality of elongated elements, each including a light reflective planar surface, the elements being arranged in first positions parallel to each other and with the light reflective surfaces of the elements lying in one or more parallel planes;

10 means for supporting the elements in relation to one another; and

means for moving a first set of the elements into second positions parallel to a second set of the elements, and between a first modulator configuration wherein said first and second sets act to reflect the incident beam of light as a plane mirror, and a second modulator configuration wherein said first and second sets diffract the incident beam of light as it is reflected from the surfaces of the elements.

20 2. A modulator as recited in claim 1, wherein the reflective surfaces of adjacent elements lie within planes separated by a distance equal to  $m/4$  times a particular wavelength of the incident beam of light, wherein  $m$  is an even whole number or zero when the elements are in the first configuration and  $m$  is an odd whole number when the elements are in the second configuration.

30 3. A modulator as recited in claim 2, wherein the means for moving the elements operates to rotate both the first set of elements and the second set of elements about axes extending generally parallel to their longitudinal dimensions when moving them relative to one another.

4. A modulator as recited in claim 2, wherein alternate elements are fixed relative to the supporting means.

-19-

5. A modulator as recited in claim 1, wherein the means for moving the first set of elements comprises means for applying an electrostatic force to the first set of elements.

5 6. A modulator as recited in claim 5, wherein the reflective surfaces are formed by metallic layers deposited on the upper surfaces of said elements.

7. A modulator as recited in claim 6, wherein the means for applying electrostatic force includes a voltage supply  
10 coupled to the metallic layers.

8. A modulator as recited in claim 2, wherein the reflective surfaces of the plurality of elements are equal in dimensions and are substantially rectangular in plan.

9. A modulator as recited in claim 3, wherein the  
15 elements are resilient.

10. A modulator for modulating a beam of incident light, comprising;

means forming a first planar light reflective surface;  
a grating having means forming a plurality of second  
20 planar light reflective surfaces, the grating being arranged with its second reflective surfaces lying in a plane parallel to and spaced from the first planar reflective surface in a direction normal thereto; and

means for moving the grating in a direction normal to  
25 said first planar reflective surface and into a position closer thereto while maintaining the second reflective surfaces of the grating substantially parallel to the first planar reflective surface;

whereby, when the spacing between the respective first  
30 and second light reflective surfaces is equal to  $m/4$  times a particular wavelength of the incident light and  $m$  is an even whole number or zero, the modulator acts to reflect

-20-

the incident light as a plane mirror, and when  $m$  is an odd whole number the modulator diffracts the incident light as it reflects it, thereby providing modulation of the beam.

5 11. A modulator as recited in claim 10, wherein the grating is comprised of a plurality of equally sized and equally spaced apart elongated rectangular elements disposed parallel to each other.

10 12. A modulator as recited in claim 11, wherein the spacing between each of the elements is substantially equal to the transverse width of each of the elements.

15 13. A modulator as recited in claim 12, wherein the spacing between the first planar reflective surface and the second planar reflective surfaces of the unmoved grating is equal to one-half the wavelength of the beam of incident light.

20 14. A modulator as recited in claim 13, wherein the means for moving the grating towards the first planar reflective surface and into the position closer thereto comprises means for applying an electrostatic force between the 5 first planar reflective surface and the second planar reflective surfaces of the grating.

15. A modulator as recited in claim 14, wherein the thickness of each element is equal to one-half the wavelength of the beam of incident light.

25 16. A modulator as recited in claim 11 wherein each said element of the grating is comprised of a deformable resilient material.

17. A method of modulating a beam of light, comprising the steps of:

-21-

causing the beam to impinge upon a plurality of equally spaced apart elements, each including an elongated, light reflective planar surface, the elements being arranged parallel to each other and with the light reflective surfaces of the elements being parallel to each other; and

moving some of the elements relative to others between a first configuration wherein the incident beam of light is reflected as by a plane mirror, and a second configuration wherein the incident beam of light is diffracted as it is reflected from the elements.

18. A method as recited in claim 17, wherein in the second configuration the said some of the elements are moved to positions wherein the spacing between the planes of the reflective surfaces of adjacent elements is equal to  $m/4$  times a particular wavelength of the incident beam of light, wherein  $m$  is an even whole number or zero when the elements are in the first configuration, and  $m$  is an odd whole number when the elements are in the second configuration.

19. A method as recited in claim 18, wherein the thickness of each element is equal to one-half the wavelength of the beam of incident light.

20. A method as recited in claim 19, wherein the said some of the elements are caused to move relative to the other elements by applying electrostatic forces to said some of the elements.

21. A modulator for modulating an incident beam of light, comprising:  
a plurality of equally spaced apart elements, each including a light reflective planar surface, the elements being arranged parallel to each other and with the light

-22-

reflective surfaces of the elements lying in at least one first plane;

means for supporting the elements in relation to one another; and

5 means for moving alternate ones of the elements relative to the other elements and between a first configuration wherein all elements lie in said first plane(s) and the modulator acts to reflect the incident beam of light as a plane mirror, and a second configuration  
10 wherein alternate elements lie in at least one second plane parallel to the first plane(s) and the modulator diffracts the incident beam of light as it is reflected from the planar surfaces of the elements.

22. A modulator as recited in claim 21, wherein said  
15 means for moving includes means for selectively: applying electro-static forces to said alternate ones of said elements.

23. A modulator as recited in claim 22, wherein the  
20 reflective surfaces of adjacent elements lie within planes separated by a distance equal to  $m/4$  times a particular wavelength of the incident beam of light, wherein  $m$  is an even whole number or zero when the elements are in the first configuration and  $m$  is an odd whole number when the elements are in the second configuration.

25 24. A modulator as recited in claim 23, wherein the means for moving the elements operates to rotate both the first set of elements and the second set of elements about axes extending generally parallel to their longitudinal dimensions when moving them relative to one another.

30 25. A modulator as recited in claim 24, wherein said other elements are fixed relative to the support means.

-23-

26. A modulator as recited in claim 21, wherein the means for moving said first set of elements comprises means for applying an electrostatic force thereto.

5 27. A modulator as recited in claim 26 wherein the first set of elements are formed of a deformable resilient material.

10 28. A modulator as recited in claim 26 wherein said first set of elements has a hysteretic characteristic such that following application of a first electrostatic force thereto to move it into said second configuration, a second electrostatic force of lesser magnitude than that of said first electrostatic force can be used to hold said first set of elements in said second configuration.

15 29. A modulator as recited in claim 14 wherein said grating has a hysteretic characteristic such that following application of said electrostatic force said 4 grating can be held in the closer position by a reduced electrostatic force.

20 30. A modulator as recited in claim 22 wherein following application of a first electrostatic force to said alternate ones of said elements, application of a second electrostatic force less than said first electrostatic force can be used to hold said alternate ones in said second configuration.

25 31. A modulator as recited in claim 10 wherein said means for moving includes means for selectively applying particular electrostatic forces to discrete groups of said means forming said second reflective surfaces.

30 32. A modulator as recited in claim 10 wherein the grating is comprised of a plurality of equally sized rectangular elements configured such that an incident beam of light

-24-

directed normal to said light reflective surfaces is reflected back along the incident ray path when said first set of elements are in said first configuration, and the incident beam is angularly diffracted relative to said incident ray path when said first set of elements are in said second configuration, the angularly diffracted beam lying in a plane including said incident ray path and transversely intersecting said elements.

33. A modulator as recited in claim 1 and further comprising means for moving a third set of the elements relative to a fourth set of the elements and between

a third modulator configuration wherein said third and fourth sets act to reflect the incident beam of light as a plane mirror, and

a fourth modulator configuration wherein said third and fourth sets diffract the incident beam of light as it is reflected from the surfaces thereof, wherein said means for moving includes means for selectively applying electrostatic forces to particular groups of said first set of elements.

34. A modulator as recited in claim 10 wherein an incident beam of light directed normal to said light reflective surfaces is reflected back along the incident beam path when said grating is in one position, and said incident beam of light is angularly diffracted relative to said incident beam path when said grating is moved to another position.

35. A modulator as recited in claim 21 wherein said means for moving includes means for selectively moving particular groups of said alternate ones of said beam elements such that a detector placed in the path of the diffracted beam will detect a beam intensity proportional to certain characteristics of the particular groups moved.

-25-

36. A modulator as recited in claim 21 wherein an incident beam of light directed normal to said light reflective surfaces is reflected back along the incident beam path when said alternate ones of said elements are in said first configuration, and said incident beam is diffracted at an angle to said incident beam path when said alternate ones of said elements are in said second configuration.

37. In a light modulating device including an array of individual light modulators for modulating an incident beam of light to generate an image, each pixel of which has a luminous characteristic corresponding to a physical characteristic of a corresponding modulator in the array, an improved modulator comprising:

a plurality of elongated elements, each including a light reflective planar surface, the elements being arranged parallel to each other and with the light reflective surfaces of the elements lying in one or more parallel planes;

means for supporting the elements in relation to one another; and

means for moving a first set of the elements in a direction normal to said planes and relative to a second set of the elements and between a first modulator configuration wherein said first and second sets act to reflect the incident beam of light as a plane mirror, and a second modulator configuration wherein said first and second sets diffract the incident beam of light as it is reflected from the surfaces of the elements.

38. In a light modulating device including an array of individual light modulators for modulating an incident beam of light to generate an image, each pixel of which has a luminous characteristic corresponding to a physical characteristic of a corresponding modulator in the array, an improved modulator comprising:

means forming a first planar light reflective surface;

-26-

a grating having means forming a plurality of second planar light reflective surfaces, the grating being arranged with its second reflective surfaces lying in a plane parallel to and spaced from the first planar reflective surface in a direction normal thereto; and

means for moving the grating in a direction normal to said first planar reflective surface while maintaining the second reflective surfaces of the grating substantially parallel to the first planar reflective surface;

whereby, when the spacing between the respective first and second light reflective surfaces is equal to  $m/4$  times a particular wavelength of the incident light and  $m$  is an even whole number or zero, the modulator acts to reflect the particular wavelength of the incident light as a plane mirror, and when  $m$  is an odd whole number the modulator diffracts the particular wavelength of the beam of incident light as it reflects it, thereby providing modulation of the beam.

39. In a light modulating device including an array of individual light modulators for modulating an incident beam of light to generate an image, each pixel of which has a luminous characteristic corresponding to a physical characteristic of a corresponding modulator in the array, an improved modulator comprising:

a plurality of equally spaced apart elements, each including a light reflective planar surface, the elements being arranged parallel to each other and with the light reflective surfaces of the elements lying in a first plane;

means for supporting the elements in relation to one another; and

means for moving alternate ones of the elements relative to the other elements and between a first configuration wherein all elements lie in the first plane and the modulator acts to reflect the incident beam of light as a plane mirror, and a second configuration wherein alternate elements lie in a second plane parallel to the

-27-

first plane and the modulator diffracts the incident beam of light as it is reflected from the planar surfaces of the elements.

5 40. In a light modulating device including an array of individual light modulators for modulating an incident beam of light to generate an image, each pixel of which has a chromatic characteristic corresponding to a physical characteristic of a corresponding modulator in the array, an improved modulator including at least three modulation  
10 components each of which is comprised of:

a plurality of elongated elements, each including a light reflective planar surface, the elements being arranged parallel to each other and with the light reflective surfaces of the elements lying in one or more  
15 parallel planes;

means for supporting the elements in relation to one another; and

means for moving a first set of the elements in a direction normal to said planes and relative to a second  
20 set of the elements and between a first modulator configuration wherein said first and second sets act to reflect the incident beam of light as a, plane mirror, and a second modulator configuration wherein said first and second sets diffract the incident beam of light as it is  
25 reflected from the surfaces of the several elements,

each said modulation component being designed to diffract a different color into an optical system when illuminated with a beam of white light.

30 41. In a light modulating device including an array of individual light modulators for modulating an incident beam of light to generate an image, each pixel of which has a chromatic characteristic corresponding to a physical characteristic of a corresponding modulator in the array, an improved modulator including at least three modulation  
35 components each of which is comprised of:

-28-

means forming a first planar light reflective surface;  
a grating having means forming a plurality of second  
planar light reflective surfaces, the grating being  
arranged with its second reflective surfaces lying in a  
plane parallel to and spaced from the first planar  
reflective surface in a direction normal thereto; and

means for moving the grating in a direction normal to  
said first planar reflective surface while maintaining the  
second reflective surfaces of the grating substantially  
parallel to the first planar reflective surface;

whereby, when the spacing between the respective first  
and second light reflective surfaces is equal to  $m/4$  times  
a particular wavelength of the incident light and  $m$  is an  
even whole number or zero, the modulator acts to reflect  
the particular wavelength of the incident light as a plane  
mirror, and when  $m$  is an odd whole number the modulator  
diffracts the particular wavelength of the beam of incident  
light as it reflects it, thereby providing modulation of  
the beam,

each said modulation component being designed to  
diffract a different color into an optical system when  
illuminated with a beam of white light.

42. In a light modulating device including an array of  
individual light modulators for modulating an incident beam  
of light to generate an image, each pixel of which has a  
chromatic characteristic corresponding to a physical  
characteristic of a corresponding modulator in the array,  
an improved modulator including at least three modulation  
components each of which is comprised of:

a plurality of equally spaced apart elements, each  
including a light reflective planar surface, the elements  
being arranged parallel to each other and with the light  
reflective surfaces of the elements lying in a first plane;

means for supporting the elements in relation to one  
another; and

-29-

means for moving alternate ones of the elements relative to the other elements and between a first configuration wherein all elements lie in the first plane and the modulator act to reflect the incident beam of light as a plane mirror, and a second configuration wherein alternate elements lie in a second plane parallel to the first plane and the modulator diffracts the incident beam of light as it is reflected from the planar surfaces of the elements,

each said modulation component being designed to diffract a different color into an optical system when illuminated with a beam of white light.

43. A modulator for modulating a beam of incident light, the modulator comprising:

a substrate;

a planar light reflective surface formed on the substrate;

a deformable grating having a planar light reflective surface, the deformable grating being arranged with its reflective surface being parallel to and spaced from the planar reflective surface on the substrate;

means for moving the grating towards the substrate while at the same time maintaining the reflective surface of the grating substantially parallel to the planar reflective surface on the substrate; and

means for preventing the grating from sticking to the substrate when the grating is moved towards the substrate;

whereby, when the perpendicular spacing between the respective light reflective surfaces is equal to  $m/4$  times the wavelength of the incident light and  $m$  is an even whole number or zero the modulator acts to reflect the incident light as a plane mirror and when  $m$  is an odd whole number the modulator diffracts the incident light as it reflects it, thereby providing the modulation of the beam of light.

-30-

44. A modulator as recited in claim 43, wherein the grating comprises a plurality of equally sized and equally spaced apart parallel rectangular grating elements having an underside, and wherein the means for preventing the grating elements from sticking to the substrate includes  
5 ridges positioned between the underside of the grating elements and the substrate.

<p>(54) Title: <b>MODULATING A LIGHT BEAM</b></p> <div data-bbox="378 1192 1268 1682"> </div> <p>(57) Abstract</p> <p>A modulator (10) for modulating incident rays of light, the modulator having several equally spaced beam elements (18), each having a light reflective planar surface. The beam elements are arranged and supported (12) parallel to each other, with their reflective surfaces parallel. During operation, the elements remain parallel, but the modulator moves the beams so that the perpendicular spacing of their reflective surfaces changes between two configurations. In both configurations, the spacing equals <math>m/4</math> times the wavelength of incident light. In the first configuration, <math>m</math> equals an even whole number or zero, and the modulator acts to reflect the incident rays of light as a plane mirror. In the second configuration, <math>m</math> equals an odd number and the modulator diffracts the incident rays as they are reflected.</p>

**BEST AVAILABLE IMAGES**

Defective images within this document are accurate representations of the original documents submitted by the applicant.

Defects in the images include but are not limited to the items checked:

- ☐ BLACK BORDERS
- ☐ IMAGE CUT OFF AT TOP, BOTTOM OR SIDES
- ☐ FADED TEXT OR DRAWING
- ☐ BLURRED OR ILLEGIBLE TEXT OR DRAWING
- ☐ SKEWED/SLANTED IMAGES
- ☐ COLOR OR BLACK AND WHITE PHOTOGRAPHS
- ☐ GRAY SCALE DOCUMENTS
- ☒ LINES OR MARKS ON ORIGINAL DOCUMENT
- ☒ REFERENCE(S) OR EXHIBIT(S) SUBMITTED ARE POOR QUALITY
- ☐ OTHER: \_\_\_\_\_

**IMAGES ARE BEST AVAILABLE COPY.**

**As rescanning these documents will not correct the image problems checked, please do not report these problems to the IFW Image Problem Mailbox.**
